ABSTRACT

In this study, some bacteria were isolated from the soil obtained from Ergani Makam Mountain. The isolated bacteria were defined as Bacillus simplex with the biochemical tests and 16S rRNA analysis. The optimum conditions for bacterial growth were determined as the 32th hour, 37°C and pH 7.0. While the maximum amylase activity was observed of the 72nd hour, the optimum temperature and pH of the enzyme were determined to be 37°C and 7.0 reciprocally. It was observed that the enzyme production increased with ammonium sulfate and ammonium nitrate from nitrogen sources and decreased with the addition of carbon sources. Amylase was partially purified with 70% ammonium sulfate precipitations and dialysis. When the effect of detergents was examined on the partially purified enzyme it was determined that SDS considerably inhibited and the other detergents increased the enzyme activity. It was also determined that while CaCl2 increased the activity whereas FeCl2, CuCl2, ZnCl2 and HgCl2 considerably inhibited the enzyme activity.

KEYWORDS: Bacillus simplex; α-amylase; isolation; production; partial purification; characterization

INTRODUCTION

Microorganisms in particular have been regarded as treasure of useful enzymes [1]. The reason is that microorganism-based enzymes can easily be obtained, do not constitute unwanted waste product, are more stable and economic, can be obtained in high purity and high quantity [2,3]. Among microorganisms, mostly, some Bacillus species and subspecies that can be found widely in the nature are used. α-Amylase, β-amylase, xylanase, alkaline phosphatase, β-glucanase (cellulase), glucose isomerase, β-lactamase, neutral protease and pullulanase can be counted among the primary enzymes synthesized by Bacillus [4].

The enzyme industry as we know it today is the result of a rapid development seen primarily over the past four decades thanks to the evolution of modern biotechnology [5,6]. The first enzyme produced industrially was α-amylase that was used for medicinal purposes. α-Amylase (EC 3.2.1.1,1,4-α-D-glucan-glucanohydrolase) is an extracellular enzyme that hydrolyzes starch and glycogen molecules [7]. It breaks the α-1,4 bonds in starch molecule into glucose, maltose, maltotriose and α-limit dextrine. It is primarily used in food industry for preparation of maltose syrup, purification and clarification of various drinks and production of bread and beer. Besides, it has a wide area of usage like paper, detergent and textile industries and pharmaceuticals [8,9,10,11].

α-Amylase, which has economical, industrial importance was produced from Bacillus simplex which is isolated from soil. Characterization of the partially purified enzyme has been performed.

MATERIAL AND METHODS

Microorganism and Culture Conditions. Bacillus simplex, isolated from the soil was produced in 120 rpm, pH 7.0 37°C and NB environment for 72 hours.

Morphological and Biochemical Tests. A test for the morphological and physiological identification of the obtained isolation was conducted. Gram, and spore staining methods and motility tests were used in order to determine the characteristics of the bacterium. Through biochemical tests (starch, gelatin and casein hydrolysis, catalase, urease and lipase activities, etc.) some characteristics of the isolates were determined and comparison was made.

α-Amylase Activity Assay. The enzyme activity was measured by DNS according to the method described by Bernfeld using 0.5% starch dissolved in a 0.1 M Tris–HCl buffer pH 7.0, for 30 min at 37°C. One unit of amylase activity was defined as the amount of enzyme that released 1 μmol of reducing end groups per minute at 37°C [12].

Determination of Protein Content. The protein content was determined by the method of Lowry [13].

Effect of Temperature, pH and Incubation
Time on Microorganism and Amylase Production. Temperature values increasing from 15°C to 55°C with 5°C intervals were tried to investigate the effect of temperature on the production of bacteria and enzyme. Samples obtained were measured in spectrophotometer. Bacteria and enzyme production was made in various pH ranges from pH 2.0 to pH 11.0 for pH effect. For the effect of incubation time on microorganism development and enzyme production; bacteria were cultivated in NB (Nutrient broth) and measured in spectrophotometer between 4th and 96th hours at 4 hours intervals.

Effect of pH and Temperature on Enzyme Activity. Incubated culture of Bacillus simplex in NB was centrifuged for the pH effect. To define the optimum pH of α-amylase in the obtained supernatant; enzyme activity was measured with the usage of substrate prepared in 0.1 M citric acid (pH 4.0-6.0), 0.1 M Tris-HCl buffer (pH 7.0-9.0) and 0.1 M carbonate/bicarbonate (pH 10.0-11.0) buffers. Besides, the effect of temperature on amylase activity was investigated with enzyme activity measurement in various temperatures from 25°C to 55°C at 5°C intervals.

Effect of Carbon and Nitrogen Sources on Enzyme and Bacteria Production. Glucose, galactose, fructose, lactose, soluble starch, maltose and sucrose from the carbon sources at a concentration of 1% were added to 25 ml NB in 100 ml erlenmeyer flasks. The effect of carbon sources on enzyme and bacteria production was determined by incubation in optimal conditions with spectrophotometric measurements.

After adding peptone, tryptone, urea, ammonium sulfate, ammonium chloride, ammonium nitrate, sodium nitrate, beef extract, yeast extract, it was incubated in optimal conditions and measured in spectrophotometer.

Partial Purification of α-Amylase. Bacteria cultivation was made in NB and incubated in 37°C temperature for 72 hours. After the incubation, it was centrifuged in 10 000 rpm for 15 minutes. Two following processes were applied in the partial purification of the enzyme. The processes were precipitated with ammonium sulfate and dialysis.

Ammonium Sulfate Precipitation. Ammonium sulfate [(NH₄)₂SO₄] of 40% and 70% respectively added to the supernatant in a sterile beaker. Afterwards, the mixture was centrifuged in a frigorific centrifuge in 10 000 rpm for 15 minutes.

Dialysis. Pellet was dissolved in 0.1 M pH 7.0 Tris-HCl buffer, transferred to the dialysis tube and dialyzed against the same buffer in 4°C for overnight.

Determination of Thermal Stability and pH Stability. For the determination of pH stability of α-amylase enzyme, 0.1 M citric, 0.1 M. Tris- HCl, 0.1 M carbonate / bicarbonate (10.0 and 11.0) were prepared. The enzyme was pre-incubated in different buffers for 180 minutes. After the pre-incubation, substrate was added and the enzyme activity was measured under the experimental conditions.

To determine the temperature stability (thermal stability) of partially purified α-amylase enzyme, enzyme alone was pre-incubated in 30°C, 40°C and 50°C temperature values for 15-120 minutes. After pre-incubation, enzyme activity specification was made.

Effect of Some Metals on Enzyme Activity. In order to determine the effect of some metals on enzyme activity, 1.5 mM concentration in overall volume from the 50 mM-stock solutions of CaCl₂, CuCl₂, ZnCl₂, MgCl₂, HgCl₂, MnCl₂ and FeCl₂ were prepared in 0.1 M pH 7.0 Tris-HCl buffer. After 30 minutes of pre-incubation, substrate was added and α-amylase activity was tested.

Effect of Some Detergents on Enzyme Activity. To investigate the effect of some detergents on partially purified enzyme activity, in the ratio of %0.5 SDS, Tween-40, Tween-80 and TritonX-100 were used. These detergents were prepared in 0.1 M pH 7.0 Tris-HCl buffer and pre-incubated for 30 minutes. Then, substrate was added and left to α-amylase activity.

RESULTS AND DISCUSSION

In this study, Bacillus simplex was isolated from the soil obtained from Ergani Mağan Mountain and α-amylase production, partial purification and characterization were performed.
**Morphological and Biochemical Tests.** It was determined that the obtained isolate is gram-positive and has rod-shaped cells with the ability to form spores (Table 1).

The microorganism was identified by biochemical tests and 16S rRNA sequence. The 16S rRNA analyses of the obtained isolates were conducted by Ref-Gen (METU Technocity/Ankara). The 16S rRNA sequence of this strain is:

**FIGURE 1**

**Effect of temperature on bacterial growth and enzyme activity**

Effect of Temperature, pH and Incubation Time on Microorganism and Amylase Production. To investigate the effect of temperature on bacteria reproduction and enzyme production, it was incubated between 15°C and 55°C. It was determined that maximum bacteria reproduction and enzyme production were observed at 37°C (Fig. 1).

Temperature is related with microorganism growth and therefore, α-amylase production. Wide temperature range (35-80°C) was given for the optimum bacterial growth and α-amylase production by many researchers.

In the bacteria culture produced in various pH at 37°C, the best bacteria reproduction and amylase production was determined at pH 7.0 (Fig. 2).

pH of the growth environment among the physical parameters has an important role for the morphological changes of microorganism, therefore the increase of enzyme synthesis.
For the effect of incubation time on microorganism development and enzyme production, a sample was taken at 4 hour intervals from the bacteria culture that was produced in 37°C NB, between 4th and 96th hours. As seen in the Fig. 3, the optimum incubation time for *Bacillus simplex* was determined to be 72 hours.

Hamilton et al. [14] determined the optimum incubation time at 41 hours, and temperature to be 40°C for *Bacillus sp.* IMD 43 production. Asgher et al. [15] determined incubation time to be 48 hours, temperature to be 50°C and pH to be 7.0 of thermophilic *Bacillus subtilis* JS-2004.

**Effect of Temperature and pH on Enzyme Activity.** To investigate the effect of temperature on α-amylase enzyme secreted by *Bacillus simplex*, bacteria were incubated in NB (pH 7.0) at 37°C that was the optimum incubation temperature for 72 hours that was the optimum incubation time. α-Amylase activity was measured with temperature increase in the obtained supernatant from 25 °C to 55°C, according to Bernfeld method [12]. The highest α-amylase activity of *Bacillus simplex* was determined between 35°C and 40°C, the optimum temperature of the enzyme was determined at 37°C (Fig. 4).

It was determined that the enzyme obtained from the bacteria produced in optimum conditions were active between pH 5.0 and pH 11.0. Increase of the enzyme activity was observed starting from pH 5.0 whereas decrease of the enzyme activity was determined up to 7.0. As seen in the Figure 5, the optimum pH of α-amylase enzyme was determined to be 7.0.
Similar results were also implied by some other researchers. Noman et al. [16] studied on the purification of α-amylase enzyme from Pachyrhizus erosus L. They determined the optimum pH of the enzyme at 7.3 and temperature to be 37°C. Sudharhsan et al. [17] investigated the psychical and nutritional factors that affect the amylase production in the Bacillus species isolated from rotten food garbage, analyzed the effects of temperature and pH factors psychically and stated that the maximum enzyme activity was observed at pH 7.0 and 37°C.

The optimum pH of extracellular α-amylases varies between 3.0 and 10. In many studies, the optimum pH of α-amylases obtained from bacteria and fungi are stated as acidic and neutral [2]. Due to its usage in the areas such as liquefaction of starch, food industry and dry cleaning, the neutral pH is essential in such processes. The fact that α-amylase of Bacillus simplex exhibit maximum activity in neutral conditions that means it is usable in industrial processes.

Effect of Carbon and Nitrogen Sources on Enzyme and Bacteria Production. In the conducted research, when control was compared with other carbon sources, it was determined that glucose and galactose showed close activity to control while the amylase activity importantly reduced in other carbon sources. For bacteria reproduction, when control was compared to other carbon sources, it was determined that reproduction in all carbon sources was higher than control (Fig. 6).

As seen in the Fig. 7, when control was compared with other nitrogen sources, lower amylase activity was obtained in all nitrogen sources than control. The highest specific activity among nitrogen sources was obtained in the culture environment with ammonium nitrate and ammonium sulfate. In bacterial reproduction, an increase was observed in all nitrogen sources with regards to control.
Behal et al. [18] produced α-amylase from Bacillus sp. AB 04 in nutrient media that has 1% fructose of carbon sources and 1% beef extract of nitrogen sources. Saxena et al. [19] acquired maximum specific activity in nutrient media that has (%) 0.6 starch, and 0.5 peptone 0.3 yeast extract for high thermostable amylase produced from Bacillus sp. PN5. Carvalho et al. [20] implemented the maximum production from therophilic Bacillus sp. SMIA-2 in nutrient media with peptone as the nitrogen source and soluble starch as the carbon source. Prakash et al. [21] determined the best α-amylase production from halophilic Chromohalobacter sp. TVSP 101 bacteria in the media with tripton as the nitrogen source.

**Partial Purification of Amylase.** After the determination of optimum conditions of Bacillus simplex α-amylase, enzyme was partially purified. Bacteria culture produced in optimum conditions was centrifuged in a frigorific centrifuge in 10 000 rpm for 10 minutes. Ammonium sulfate [(NH₄)₂SO₄] in 70% saturation level was added with stirring to the supernatant in a sterile beaker. Subsequently the mixture was centrifuged in 10 000 rpm for 15 minutes. Obtained pellet was dissolved in 0.1 M pH 7.0 Tris-HCl buffer, transferred to the dialysis tube and was dialyzed over night.

**Effect of Metals.** When the effect of some metals on partially purified enzyme activity was analyzed, it was determined that CaCl₂ (113%)
increased the activity; no change was observed after adding MnCl$_2$ (100%) and MgCl$_2$ (92%); FeCl$_2$ (61%) partially inhibited and CuCl$_2$ (22%), ZnCl$_2$ (24%), HgCl$_2$ (16%) strongly inhibited the enzyme activity (Table 2).

Shafiei et al. [22] biochemically characterized the amylase enzyme excreted from Nesterenkonia sp. F strain. They determined that Zn$^{2+}$, Fe$^{3+}$, Cu$^{2+}$ and Al$^{3+}$ ions inhibited the amylase activity while Ca$^{2+}$ increased the it. Noman et al. [16] determined that Zn$^{2+}$, Fe$^{3+}$ and Cu$^{2+}$ ions make inhibition effect in high rate while Li$^{+}$, Hg$^{2+}$ and Cd$^{2+}$, Ag$^{+}$, Mg$^{2+}$ and K$^+$ ions have low effects on activity. Srivastava [23] determined that Cu$^{2+}$, Fe$^{3+}$, Ni$^{2+}$, Hg$^{2+}$, Pb$^{2+}$ and Ag$^{+}$ ions completely inhibited the activity of purified amylase, but Ca$^{2+}$, Ba$^{2+}$, Sr$^{2+}$ and K$^+$ ions increased it. The results obtained from conducted studies support the findings we obtained from our study.

**Effect of Detergents.** To investigate the effect of some detergents on partially purified α-amylase enzyme activity, SDS in the ratio of 0.5%, Tween-40, Tween-80 and TritonX-100 were used. Rest of the enzymes were compared with the control and their relative activities were calculated. According to the control, the amount of rest of the enzymes were determined to be; SDS 12%, Tween-40 134%, Tween-80 138% and TritonX-100 140% (Fig. 8). While the inhibition was observed only with the SDS effect, the inhibition having not been observed with other detergents shows the the resistance to detergents.

Asoodeh et al. [24] determined that α-amylase activity they purified from thermophilic *Bacillus sp. ferdowsicus* increased with Triton X-100. Shafiei et al. [22] determined that amylase was considerably stable to SDS, Triton X-100, Tween 80 and Tween 20 detergents.

In the literature, because disulfide bonds are found in the enzyme and becoming unstable to oxidation due to the amino acids undergoing a change by oxidation; it is stated that the thermostability of the enzyme increases and thus the enzyme is not affected by the oxidizing agents.

This result obtained suggests that the enzyme is not affected by oxidant agents, the amino acids change with heat and cause resistance.

**pH and Temperature Stability.** 25 μl enzyme and various buffers prepared in 50 μl were left and pre-incubation was done for 60 minutes. α-Amylase activity specification was made with substrate adding after pre-incubation. It was observed that pH stability of enzyme activity increased after pH 5.0 and started to decrease after pH 7.0. As seen in the Fig. 9, pH stability was found to be 7.0. To determine the temperature stability of partially purified enzyme, enzyme was pre-incubated in 30°C, 40°C and 50°C temperature values for 15, 30, 45, 60 and 120 minutes. After pre-incubation, enzyme activity specification was made. Partially purified enzyme was determined to be stable in 30°C, 40°C and 50°C after 2 hours (Fig.10).
Bernhardsdotter et al. [25] detected that when the isolated amylase was pre-incubated in 37°C, between pH 7.0 and 11.0 for 1 hour, it lost the 20% percent of its original activity.

Wang et al. [26] detected that the purified amylase's pH stability was between 6.0 and 11.0 and its temperature stability was under 60°C.

CONCLUSION

Studies about industrial enzymes are becoming more important since the enzyme technology is developing. Therefore, in our study, amylase which has a great industrial importance was produced easily and economic processes and was partially purified in optimum conditions.
